Internet Protocol version 6 (IPv6) Header

Lecture Contents

- Review of IPv4 Header
- IPv6 header
- IPv6 Addresses
- IPv6 Fragmentation

Internet Protocol version 6 (IPv6)

- Solve the problem of IPv4 address exhaustion
 - IPv4 only ~4 billion addresses, IPv6 $\sim 3.4 \times 10^{38}$ addresses
- Not designed to be interoperable with IPv4
 - Slows transition from IPv4 to IPv6
- Hierarchical address allocation facilitate route aggregation (?)
 - Reduce routing table size
- Multicast simplified and expanded (?)
- Device mobility, security, configuration considered in design (?)

Internet Protocol version 6 (IPv6) Header

- IPv6 header
 - first defined in *RFC1883* in December 1995
 - Standardized in *RFC 8200*, July 2017

Review of IPv4 Header

- IPv4 header given in *IEN 54* (and *RFC 760*)

Internet Protocol version 6 (IPv6) Header

- **Version** set to 6: 0110
- **Traffic Class / Flow Label**
 - Intended for QOS (Quality of Service) uses for special handling of packets
 - Allows special handling by intermediate IPv6 routers
 - Set to zero if router/host does not support
 - Flows must be set up
 - supposed to specify lifetime of the flow.

- No header length
 - Why?

Version	IHL	ToS	Total Length	
Identification			Flags	Fragment Offset
Time To Live	Protocol		Header Checksum	
Source Address				
Destination Address				
Options				Padding

- No header length
 - IPv6 header is fixed 40 octets

Version	HL	ToS	Total Length	
Identification			Flags	Fragment Offset
Time To Live	Protocol		Header Checksum	
Source Address				
Destination Address				
Options				Padding

- No header length
 - IPv6 header is fixed 40 octets
- No fragmentation fields
 - Then how to solve?

- No header length
 - IPv6 header is fixed 40 octets
- No fragmentation fields
 - Fragmentation at endpoints

The diagram illustrates the structure of an IPv4 header, which is 20 octets long. It is divided into several fields: Version (4 octets), IHL (4 octets), ToS (4 octets), Total Length (4 octets), Identification (4 octets), Flags (2 octets), Fragment Offset (4 octets), Time To Live (4 octets), Protocol (4 octets), Header Checksum (4 octets), Source Address (4 octets), Destination Address (4 octets), Options (0-40 octets), and Padding (0-16 octets). A red line is drawn across the Identification, Flags, and Fragment Offset fields, indicating that these fields are not used in IPv6.

Version	IHL	ToS	Total Length	
Identification		Flags	Fragment Offset	
Time To Live		Protocol	Header Checksum	
Source Address				
Destination Address				
Options			Padding	

- No header length
 - IPv6 header is fixed 40 octets
- No fragmentation fields
 - Fragmentation at endpoints
- No header checksum
 - Why?

Version	IIHL	ToS	Total Length	
Identification			Flags	Fragment Offset
Time To Live	Protocol	Header Checksum		
Source Address				
Destination Address				
Options				Padding

- No header length
 - IPv6 header is fixed 40 octets
- No fragmentation fields
 - Fragmentation at endpoints
- No header checksum
 - Link layers are reliable enough
 - Less computation required of nodes (why?)
 - Payload has own error checking and correcting, as necessary

Version	HL	ToS	Total Length	
Identification			Flags	Fragment Offset
Time To Live	Protocol		Header Checksum	
Source Address				
Destination Address				
Options				Padding

- Fixed header length
- Fragmentation at endpoints
- No header checksum
- Approximate equivalents:

- *Type of Service* → *Traffic Class / Flow label* (QOS – Quality of Service)
- *Total Length* → *Payload Length*
- *Time to Live* → *Hop Count*
- *Protocol* → *Next Header*

Internet Protocol version 6 (IPv6) Header

- IPv6 header defined in

Total length: **Ten** 32-bit words
(= 40 octets = 320 bits)

Minimum length: **Five** 32-bit words
(= 20 octets = 160 bits)

Maximum: **Fifteen** 32-bit words
(= 60 octets = 480 bits)

Note: four bit field, and 0xF is 15

Internet Protocol version 6 (IPv6) Addresses

- 128 bits → 32 hexadecimal digits
 - Written as $x:x:x:x:x:x:x:x$, where each x is 1-4 hexadecimal digits
 - Two colons “: :” can replace one or more groups of 16 bits of zeros, but can only appear once
 - Examples:
 - $2001:DB8:0:0:8:800:200C:417A \rightarrow 2001:DB8::8:800:200C:417A$
 - $FF01:0:0:0:0:0:0:101 \rightarrow FF01::101$
 - $0:0:0:0:0:0:0:1 \rightarrow ::1$ ← the *loopback address*; IPv4 is 127.0.0.1
 - $0:0:0:0:0:0:0:0 \rightarrow ::$ ← the *unspecified address*; host with no address
 - Can also use IPv4 format for last 2 bytes: $0:0:0:0:0:0:13.1.68.3$

Internet Protocol version 6 (IPv6) Addresses

- IPv6 Prefixes follow *Classless Inter-Domain Routing* (CIDR) notation
 - *Address / prefix-length*
 - Examples for 60-bit prefix: 2001:0DB8:0000:CD30:0000:0000:0000:0000/60
 - 2001:0DB8:0000:CD30:0000:0000:0000:0000/60
 - 2001:DB8::CD30:0:0:0:0:0/60
 - 2001:DB8:0:CD30::/60
 - Illegal:
 - 2001:0DB8:0:CD3/60 ← expands to 2001:0DB8:0:0CD3:0:0:0:0
 - 2001:0DB8::CD30/60 ← expands to 2001:0DB8:0:0:0:0:0:CD30
 - 2001:0DB8::CD3/60 ← expands to 2001:0DB8:0:0:0:0:0:0CD3

Internet Protocol version 6 (IPv6) Addresses

- IPv6 node address and subnet number can be combined:
 - Example
 - node address: 2001:0DB8:0:CD30:123:4567:89AB:CDEF
 - Subnet prefix: 2001:0DB8:0:CD30::/60
 - Combined: 2001:0DB8:0:CD30:123:4567:89AB:CDEF/60

Internet Protocol version 6 (IPv6) Addresses

- IPv6 address type:

Unspecified:	::/128	00...0 (upper 128 bits all zero)
Loopback:	::1/128	00...1 (upper 127 bits zero then a 1)
Multicast:	FF00::/8	11111111 (upper 8 bits all 1)
Link-local unicast:	FE80::/10	1111111010 (upper bits 7 ones then 010)
Global Unicast:	<i>everything else</i>	

Internet Protocol version 6 (IPv6) Fragmentation

- All nodes on IPv6 network required to at least handle packets up to 1280 octets in size
 - IPv4 is 576 bytes (64+512); minimum 68 bytes without fragmentation
- Routers do *not* fragment IPv6 packets
 - Too large → drop and send back **ICMPv6 Packet Too Big** message
- ***Path MTU Discovery***
 - Endpoints are “strongly recommended” to use to take advantage of greater packet lengths
 - **MTU** = Maximum Transmission Unit
 - Maximum packet length that can be transmitted without need for fragmentation
